

ABSTRACT

A method for establishing calls in a communications network comprising a fixed network section and a mobile network section is provided. In the fixed network section, all calls to mobile called party addresses subscribers are signaled to a fixed network node capable of querying a home location register of the mobile network section. At that node, the home location register is queried and a roaming number is provided. The roaming number is then used for directly establishing a call from a calling fixed network subscriber to the mobile called party.
